Oak Ridge, Tennessee 37831-6036

ABSTRACT

Lovets Pond is a wetland ecosystem located in the Mississippi River floodplain of Jackson County, Illinois. Systematic collecting of the vascular flora at the site reveal 328 species, subspecies, and varieties, representing 199 genera and 86 families. Six natural community types are found in the 60 ha ecosystem: pond, shrub swamp, true swamp, marsh, wet-mesic floodplain forest, and successional field. The pond, shrub swamp, true swamp, and marsh communities at the site are rare in the region. The present natural character of Lovets Pond is similar to the earliest known presettlement descriptions. The rarity of the wetland community types and the high natural quality of the site are two major factors in distinguishing Lovets Pond as a valuable natural resource for the region.

INTRODUCTION

North of the coastal floodplain and south of the confluence of the Mississippi and Missouri rivers is the broad Mississippi River floodplain, historically referred to as the "American Bottoms." Lovets Pond is one of a small number of natural pond ecosystems still extant in this vast floodplain. The almost complete elimination of the once common wetlands in this region is due largely to extensive wetland drainage and land clearing for agricultural use. The only other significant natural ponds that remain are at the Larue Swamp-Wolf Lake region in Union County and at the Levee Lake site in Alexander County. Prior to this study, the Lovets Pond site in Jackson County had received little attention from biologists, and the flora at the site had never been systematically surveyed.

The primary objectives of this study are to compile a comprehensive list of the vascular flora found at Lovets Pond, to report a representative habitat for each taxon, and to qualitatively describe the natural communities at the site.

THE STUDY AREA

Lovets Pond is located approximately 10 km from the Mississippi River, near the mideastern border of Jackson County, Illinois. The boundary of the study area was established to include all natural communities associated with the pond proper (Fig. 1). The pond proper occupies about 25 ha; the surrounding floodplain forest, swamp, and marsh increase the ecosystem to approximately 60 ha. The natural community complex is completely surrounded by farmland. The Kinkaid Hills are 0.8 km to the north of the pond and are the source of three intermittent streams that enter the study area. When water levels are high, the pond drains into Glenn Creek at the southwestern end of the site.

The Mississippi Valley region encompassing Lovets Pond was classified by Schwegman (1973) as the Southern Section of the Lower Mississippi River Bottomlands Division. The section was historically characterized by a broad alluvial floodplain with river meander scars, oxbow lakes, natural levees, and terrace remnants. Lovets Pond is located in one of the abandoned meander bends of the Mississippi River at approximately 109 m above sea level (Harris et al., 1977). A linear ridge at the 111-m contour parallels the pond to the north. Slightly higher ground separates the linear ridge from the adjacent Kinkaid Hills.

The study area is underlain by limestone of Mississippian age (Willman et al., 1967). The parent material at the site is alluvium, primarily clay and silt. The Darwin, Hurst, Birds, Karnak, and Cairo series of soils occur on the site. The soils are poorly drained, silty clays to a depth of approximately 1.5 m (Soil Survey of Jackson County, Illinois, 1979).

The climate of the region is temperate with a mean annual temperature of 13.8°C at Carbondale, approximately 25 km east of the study area (Soil Survey of Jackson County, Illinois, 1979). The coldest month is usually January with an average temperature of 0.7°C. July, with an average temperature of 25.6°C, is the warmest month. The mean annual precipitation is 107.8 cm, with an average of 7 cm in January, the driest month, and 11.7 cm in May, the wettest month. There is an average of 186 frost-free days.

The presettlement vegetation of the Lovets Pond area can be partially reconstructed using the eyewitness descriptions of the landscape recorded in the Public Land Survey field notebooks (Public Land Survey 1804-1850). According to the surveyors of 1807-1810, the immediate vicinity of Lovets Pond was dominated by an interconnecting network of lakes, ponds, and swamps (Fig. 2). The ponds and lakes were flat-bottomed, relatively shallow in most areas, and open with little or no timber. Dense, shrubby thickets were prevalent along the edges. On the land adjoining the ponded areas were wet woods and swamps, where periodic flooding probably had considerable influence on the structure and composition of timber. Bottomland timber was reported to be primarily ash (*Fraxinus* sp.), elm (*Ulmus* sp.), pin oak (*Quercus palustris*), overcup oak (*Quercus lyrata*), hackberry (*Celtis occidentalis*), hickory (*Carya* sp.), maple (*Acer* sp.) and locust (*Gleditsia* sp.). Common understory species identified were ironwood (probably *Carpinus caroliniana*), spice (*Lindera benzoin* or *Sassafras albidum*) and pawpaw (*Asimina triloba*). Dividing the low, wet areas were slightly higher linear ridges, characterized by dense growths of timber and impassible underbrush.

Today the natural vegetation at Lovets Pond represents an isolated island refuge in a vast expanse of cornfields. The extensive natural wetland that was continuous with Lovets Pond has been extirpated by human activity. Fortunately, the remaining small wetland does not show the direct effects of extensive agricultural encroachment; the water is clear, the aquatic vegetation is dense, and the bottom is firm. The pond's close proximity to the Kinkaid Hills watershed and the presence of better-drained soils to the immediate north are two factors that have probably helped prevent a heavy silt load from entering the pond.

METHODS AND MATERIALS

A comprehensive plant list was compiled by traversing the study area and collecting a representative specimen of each vascular taxon encountered. After preliminary identification in the field, the specimens were pressed, dried, and a final determination made later in the laboratory. The habitat and general abundance of each taxon were noted in the field. The study site was visited about twice a week during the 1985 growing season; periodic trips were made again during the 1986 season but less frequently. Voucher specimens were deposited in the herbarium, Department of Botany, Southern Illinois University at Carbondale, and in the author's personal collection.

RESULTS AND DISCUSSION

The known vascular flora of the Lovets Pond study area consists of 328 species, subspecies, and varieties representing 199 genera and 86 families. Included are 4 pteridophytes, 96 monocots, and 228 dicots. The 4 largest families, the Asteraceae (39 species), Poaceae (36), Cyperaceae (30), and Polygonaceae (11) account for 35% of the species. *Carex* is the largest genus with 20 species, followed by *Polygonum* (8), and *Bidens* (6). The 60 woody species, including 33 trees, 18 shrubs and small trees, and 9 woody vines, make up 18% of the flora. Thirty-eight (12%) of the total number of species are nonnative; however, most of these were collected from narrow, disturbed habitats at the periphery of the study area.

Eleven plant species designated as rare or very rare in Illinois by Mohlenbrock (1986) are found at Lovets Pond: *Ammannia auriculata*, *Aster prenanthoides*, *Carex louisianica*, *Carex socialis*, *Fraxinus profunda*, *Gleditsia aquatica*, *Limnobium spongia*, *Penstemon alluviorum*, *Poa angustifolia*, *Ranunculus carolinianus*, and *Rorippa islandica*. At the time of collection, five of these species (*Aster prenanthoides*, *Carex louisianica*, *Carex socialis*, *Penstemon alluviorum*, and *Poa angustifolia*) were previously unreported from Jackson County, Illinois (Mohlenbrock and Ladd, 1978). Additionally, two species not rare in the state, *Decodon verticillatus* and *Triadenium walteri*, were new records for the county. *Carex socialis* was listed by White (1978) as an "exceptional feature." Elements given this designation are considered very rare in Illinois and add significantly to the natural quality of an area. The occurrence of *Aster prenanthoides* at Lovets Pond is approximately 300 km south of the nearest known Illinois location.

Based on a natural classification scheme for Illinois developed by White and Madany (1978), six communities are present within the study area: pond, shrub swamp, true swamp, marsh, wet-mesic floodplain forest, and successional field. The successional field and floodplain forest communities are extremely common in the Lower Mississippi River Bottomlands Division. The wetland communities (marsh, true swamp, shrub swamp, and pond) are all extremely rare. Of the 157,000 total ha in the division, no high quality swamp or marsh communities and only 75 ha of high quality pond and shrub swamp communities were documented as extant in a 1976 survey (White, 1978).

A pond community is defined as a small, still, permanent body of water usually shallow enough to allow rooted aquatic plants across most of it (White and Madany, 1978). Ponds are distinguished from other wetlands by the general lack of emergent woody or graminoid vegetation. The pond community in the Lovets Pond study area is characterized by a broad area of "open water" dominated by *Nuphar luteum* ssp. *macrophyllum*. Distributed randomly within the *Nuphar* are dense mats of *Polygonum amphibium* and *Polygonum hydropiperoides*. Floating plants, including a rich variety of duckweeds, are increasingly apparent in the pond as the summer season progresses. The floating assemblage is composed of *Azolla mexicana*, *Lemna minor*, *Lemna obscura*, *Limnobium spongia*, *Spirodela polyrhiza*, *Wolffia brasiliensis*, *Wolffia columbiana*, and *Wolffiella gladiata*. Submerged close to the surface in most areas of the pond is a dense layer of *Ceratophyllum demersum*. Extending irregularly into the ponded zone is the shrubby *Cephalanthus occidentalis*.

A shrub swamp community is a body of water dominated by woody plants consisting of at least 50% coverage by shrubs and less than 20% coverage by trees (White and Madany, 1978). The shrub swamp community at Lovets Pond forms a dense thicket around the ponded zone. Standing water is present throughout this community most of the year. *Cephalanthus occidentalis* is the dominant shrub species in this community. Shrubby species occasionally associated with the *Cephalanthus*, particularly in the shallow water areas, are *Ilex decidua*, *Cornus stolonifera*, *Carpinus caroliniana*, and *Salix rigida*. *Salix nigra* is a conspicuous tree species scattered throughout.

Very little herbaceous growth is found below the heavily shaded shrub thicket. A number of herbaceous species are found, however, in scattered openings in the brush, including *Alisma plantago-aquatica* var. *parviflorum*, *Carex grayi*, *Iris shrevei*, *Mimulus alatus*, *Nuphar luteum* ssp. *macrophyllum*, *Peltandra virginica*, *Polygonum pensylvanicum* var. *laevigatum*, *Polygonum punctatum*, and *Rumex verticillatus*. Less commonly encountered plant species found in these openings are *Carex crinita*, *Carex louisianica*, and *Penstemon alluviorum*. As the summer season progresses, floating plants (primarily duckweeds) dominate on the water's surface, as is the case in all wetland communities at Lovets Pond. An almost monotypic band of *Saururus cernuus* grows in shallow water or muddy ground at the periphery of the shrub swamp community.

A true swamp community is defined by White and Madany (1978) as a forested, permanent or semipermanent body of water. The true swamp at Lovets Pond is only about 2 ha in size and closely borders the shrub swamp and pond communities at the site. The trees are young to mature in age; numerous fallen trees and logs are scattered on the swamp floor. Shallow water was present in

the community during most of the year in 1985 and 1986. An assemblage of water-tolerant tree species characterize the true swamp: *Acer rubrum*, *Fraxinus profunda*, *Gleditsia aquatica*, *Populus heterophylla*, and *Salix nigra*. In shallow water or muddy ground *Quercus palustris* is common. Two shrubs occurring occasionally in the true swamp are *Cephalanthus occidentalis* and *Ilex decidua*.

The understory of the true swamp is dominated by dense stands of *Peltandra virginica* about 1.5 m in height. Other herbaceous species associated with the *Peltandra* include *Alisma plantago-aquatica* var. *parviflorum*, *Bidens cernua*, *Decodon verticillatus*, *Rumex verticillatus*, and *Saururus cernuus*. *Iris shrevei* occurs in small monotypic colonies in some areas. *Cuscuta gronovii* and *C. polygonorum* form a blanket over much of the herbaceous layer. Floating on the water's surface in the true swamp are *Azolla mexicana*, *Lemna minor*, *Spirodela polyrhiza*, *Wolffia brasiliensis*, *Wolffia columbiana*, and in an isolated area, *Ranunculus flabellaris*.

A marsh community is characterized by tall graminoid plants and water near or above the ground surface for most of the year (White and Madany, 1978). The marsh community at Lovets Pond is approximately 2 ha in size and is bordered by cornfield. Approximately half of the marsh community has standing water present throughout the year. Except during the driest periods, standing water in the marsh is continuous with the nearby swamp and pond. The deepest areas of the marsh are either devoid of emergent vegetation or contain isolated clumps of *Peltandra virginica*. During the early spring months submerged plants are evident in the open water, including *Callitricha heterophylla*, *Ceratophyllum demersum*, and *Potamogeton pusillus*. By summer, duckweeds, *Limnobium spongia*, and *Ludwigia peploides* ssp. *glabrescens* completely cover the water surface.

A dense growth of graminoid plants, 1.5 m to 2 m tall, is prevalent at the periphery of the deep water zones in the marsh community. *Sparganium eurycarpum* is the dominant plant in this shallow water region and throughout the moist ground. Occurring in large circular colonies within the *Sparganium* is *Scirpus tabernaemontanii*. Also associated with the *Sparganium* are *Alisma plantago-aquatica* var. *parviflorum*, *Carex hyalinolepis*, *Carex lirida*, *Eleocharis macrostachya*, *Hibiscus lasiocarpus*, *Leersia oryzoides*, *Polygonum amphibium*, *Polygonum hydropiperoides*, *Sagittaria latifolia*, *Sium suave*, and *Typha latifolia*.

Wet-mesic floodplain forest communities are found on the floodplains of streams and are determined by the frequency and duration of flooding (White and Madany, 1978). The forests are usually a mixture of trees with no clear dominants. A diverse assemblage of tree species characterizes the overstory in the floodplain forest at Lovets Pond, including *Acer saccharinum*, *Carya cordiformis*, *Carya ovata*, *Celtis laevigata*, *Celtis occidentalis*, *Fraxinus americana*, *Fraxinus pensylvanica* var. *subintegerrima*, *Gleditsia triacanthos*, *Quercus macrocarpa*, *Quercus michauxii*, *Quercus palustris*, *Ulmus americana*, and *Ulmus rubra*. Subcanopy and tall understory species found in the community are *Acer negundo*, *Asimina triloba*, *Cornus stolonifera*, *Ilex decidua*, *Lindera benzoin*, and *Ulmus alata*. Woody vines are common throughout and include *Ampelopsis cordata*, *Smilax hispida*, *Smilax rotundifolia*, *Toxicodendron radicans*, and *Vitis cinerea*.

During the spring months a monotypic colony of *Ranunculus carolinianus* is the dominant herbaceous species in the wettest zones of the floodplain forest. On the slightly drier ground in spring is a rich assemblage of wildflowers, including *Claytonia virginica*, *Corydalis flavula*, *Delphinium tricorne*, *Dentaria laciniata*, *Erythronium albidum*, *Sanguinaria canadensis*, *Trillium recurvatum*, and *Viola obliqua*. Characteristic herbaceous plants in the summer include *Boehmeria cylindrica*, *Cryptotaenia canadensis*, *Eclipta prostrata*, *Impatiens capensis*, *Lysimachia ciliata*, *Pilea pumila*, and *Ruellia strepens*. Graminoids evident in the summer are *Carex convoluta*, *Carex grayii*, *Carex lupulina*, *Carex projecta*, *Cinna arundinacea*, *Glyceria striata*, and *Leersia lenticularis*. In autumn herbs such as *Aster vimineus*, *Aster simplex*, *Bidens tripartita*, *Lobelia cardinalis*, *Lobelia siphilitica*, *Polygonum virginianum*, and *Verbesina alternifolia* are commonly encountered.

A successional field community includes any formerly disturbed open land. Examples are abandoned fields and pastures, roadsides, and vacant lots. The unifying factor is human disturbance (White and Madany, 1978). At Lovets Pond the highly disturbed areas are narrow fields and roadsides at the periphery of the study area. The flora in these habitats is a mixture of both alien and native, disturbance-adapted species. Commonly encountered woody species are *Cornus drummondii*, *Quercus imbricaria*, *Rhus glabra*, *Rosa multiflora*, *Rubus allegheniensis*, and *Sassafras albidum*. A large number of grass species characterize the successional field community, including *Echinochloa crus-galli*, *Elymus virginicus*, *Festuca pratensis*, *Poa pratensis*, *Setaria faberi*, and *S. viridis*. *Ambrosia artemisiifolia*, *Ambrosia trifida*, *Bidens aristosa* var. *retrorsa*, *Cirsium discolor*, *Erigeron annuus*, *E. strigosus*, and *Xanthium strumarium* var. *glabratum* are representative of the composites. Additional herbaceous species common in the disturbed areas are *Dianthus armeria*, *Ipomoea lacunosa*, *Juncus interior*, *J. tenuis*, *Lamium amplexicaule*, *Lonicera japonica*, *Ranunculus abortivus*, and *Rumex crispus*.

A large majority of the plant species listed for this site are representative of natural ecosystems. The aquatic community assemblages are considered rare in this natural division dominated by agriculture. Despite the surrounding agricultural encroachment, the character of the remaining Lovets Pond ecosystem is largely consistent with the earliest presettlement descriptions. Thus two major factors in distinguishing a natural area are met: (1) the site is of high natural quality and (2) the community(s) and/or species present are of significant rarity. Lovets Pond is a rare and valuable natural resource for the region.

ANNOTATED CHECKLIST

The nomenclature and sequence of taxa follow Mohlenbrock (1986). Following the binomial and authority is a brief habitat description and a statement of relative abundance for each taxon. The natural community designation pertains only to the voucher specimen and does not reflect the species occurrence in other communities. An effort was made, however, to collect the voucher specimen from the species' most typical natural community. The natural communities are abbreviated in the following list as follows: PO = pond, SH =

shrub swamp, TR = true swamp, MA = marsh, FL = wet-mesic floodplain forest, and SU = successional field. The relative abundance (based on observations and collections) is indicated in the following list as common, occasional, or rare. The designations refer to the species abundance in suitable habitat. The following abbreviations are used to represent abundance: com. = common, occ. = occasional, and rar. = rare.

<i>Xanthium strumarium</i> L. var. <i>glabratum</i> (DC.) Cronq. SU, occ.	<i>Lactuca canadensis</i> L. SU, com.
<i>Pyrrhopappus carolinianus</i> (Walt.) DC. SU, rar.	<i>Lactuca floridana</i> (L.) C. A. Mey. FL, occ.

ACKNOWLEDGEMENTS

Sincere thanks are given to Dr. Robert H. Mohlenbrock for patiently verifying original plant identifications. I am grateful to Mrs. Ernest Rodewald for access to the property. Appreciation is expressed to the Environmental Sciences Division Information Processing Center of the Oak Ridge National Laboratory, which is operated by Martin Marietta Energy Systems, Inc., under contract DE-AC05-84OR21400 with the U.S. Department of Energy. Publication No. 3459, Environmental Sciences Division, ORNL.
